# Contents

# 1 Notes on specific topics

## 1.1 Architecture

- registers
- program counter
- condition codes
- status codes
- processing cycle
- pipelining
- forwarding
- cutting in line
- out-of-order execution

## 1.2 Assembly

### 1.2.1 Labels

- `.global` labels
- `%eax` being set to zero
- section of assembly code (`.section`)

### 1.2.2 Program Basics

- why we need `push %rbp` to `call puts@plt`
- `push %rbp` and then `mov %rsp, %rbp`

- subtracting 8 from base pointer and then adding it back at the end
- what does `lea var(%rip)` do exactly
- what does `leave` do
- what does `ret` do
- order of registers for arguments to functions
- multi-register operations

### 1.2.3 Variables

- `int x 0, 0`
- plt
- position independent code
- got (global offset table)

### 1.2.4 Important Commands

- syscall vs call
- call functions
- jumps
- loops using labels

Chapter 1.1 to 1.10

Chapter 4.1 to 4.3

# 2 Lecture 27.01.2020

**Class was cancelled**

# 3 Lab 29.01.2020

- logging into the server or setting up the working environment
- we'll work with assembly files and then go ahead with stuff
- well do some linking and just optimizing a bit of asm
- `@plt` is some table that allows you to call functions from outside of your program
- topic is `position independent code`, look that up
- `plt` table has the locations of all the functions that you might want to call from you program
- `got` global offset table works with `plt` to make it happen
- `xor %eax, %eax` can also be used instead of `mov $0, %rax`, xor with itselg sets all the bits to zero in `%eax`
- `%eax` is half of `%rax`, meaning that we can set `%rax` to zero by calling `xor` on `%eax`
- well use `syscall` in lab 3 to do some stuff
- look at the `syscall` docs linked in lab 3
- number 03 will not be on the exam

# 4 Lecture 03.02.2020

- we are going to try to link the labs and the lectures together
- we're going to chapter 4 and x86-64 architecture
- learning an ISA
  - if you know how the processor works helps you understand how the whole computer works
  - understanding how CPUs work can help you write better code as well
  - helps one make decisions on hardware design
  - maybe some of us will work on actual CPU design
- registers are used as super fast short term storage
- program counter keeps track of the instructions that are being executed at the moment
- condition code
- status code indicates the overall state of the programs execution
- Y86 has immediate to memory, register to memory, memory to register, register to register moves
- logic gates are the basic components of a CPU and a PC in general, how they work is not to complicated at the basics, but it gets super complex if you have billions of them

hello_world.c

```c
#include <stdio.h>

int main() {
    puts("Hello, World!\n");
    return 0;
}
```

hello_world.asm

```
main:
    subq    $8,     %rsp
    movl    $.LC0, %edi
    call    puts
    movl    $0,     %eax
    addq    $8,     %rsp
    ret
```

sum.c

```c
long sum(long *start, long count) {
    long sum = 0;
    while (count) {
        sum += *start;
        start++;
        count--;
    }
    return sum;
}
```

sum.asm

```
sum:
    movl    $0,     %eax
    jmp     .L2
.L2:
    addq    (%rdi), %rax
    addq    $8,     %rdi
    subq    $1,     %rsi
.L3:
    testq   %rsi,   %rsi
    jne     .L3
    rep; ret
```

# 5 Lecture 10.02.2020

- every processing cycle does
  - *fetch:*
    - many modern CPUs fetch hundrets of instructions in one go and then runs through all them, they are saved in L1 cache
    -
  - *decode:*
  - *execute:*
  - *memory:*
  - *write back:*
- *fetch* and *write back* can be combined into one thing
- each cycle the `PC` (program counter) is incremented
- pipelining can be somewhat compared to a car factory – you perform the first step of the first instruction moving on to the second step, then you perform the first step of the second instruction and so on
- this can be very efficient because there is little time being wasted
- *forwarding, pipelining, cutting in line, and the other techniques*

# 6 Lab 12.02.2020

- you go to labels for conditionals and simple functions: `<name>:`
- when you call the function by `call <name>` it jumps there and executes the code
- two types of jumps: conditional (depends on some condition), unconditional (it jumps in any case)
- why does the lab not work?
